

# Organizing, documenting and distributing code

ASPP 2021, Bordeaux

Pick up your work  
after a few weeks  
of holidays

$t=0$

+3 weeks

Write code

Reviewer #2 is asking  
for additional analyses  
or a substantial change  
to your model

Pick up your work  
after a few weeks  
of holidays

Reviewer #2 is asking  
for additional analyses  
or a substantial change  
to your model

Pick up your work  
after a few weeks  
of holidays

A new PhD student in the lab  
is asked to pick up your  
old project + your old code

Reviewer #2 is asking  
for additional analyses  
or a substantial change  
to your model

You are writing your  
thesis and you need to  
re-do some figures  
of your first project

Pick up your work  
after a few weeks  
of holidays

A new PhD student in the lab  
is asked to pick up your  
old project + your old code

Write code

# Motivation

- **Organising** your code in a standardized way makes it easier to understand and increases **usability** for **you** and **future you** (and **other people**)

# Contents

- **how to organise your code ==> as a package**
  - files and folder structure
  - importing and installing your package
- **how to make code understandable ==> documentation**
- **how to handle requirements ==> virtual environments**

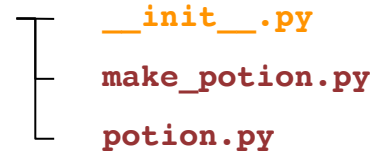

?

Package structure

# Package

- Typically a **package** is a folder (name of folder = name of package) which contains an `__init__.py` file and **modules**.

brewing

```
__init__.py  
make_potion.py  
potion.py
```

# Modules

- A **module** is a .py file consisting of Python code  
e.g. functions and/or classes  
and/or variables
- its contents can be imported

File: example\_module.py

```
""" This is a module. """

some_constant = 3.14

def some_function(x, y):
    return x + y

def ExampleClass():
    def __init__(self):
        self.greeting = "hello"
    def greet(self):
        print(self.greeting)
```

# \_\_init\_\_.py

- The `__init__.py` file marks a folder as a package
- can be empty (easiest at the beginning)
- Can be used to control importing

File: `__init__.py`

# Package

- Typically a **package** is a folder (name of folder = name of package) which contains an `__init__.py` file and **modules**.
- A **package** may also contain other **packages**
- the packages you know (numpy, scipy, sklearn, ...) follow this structure

brewing

`__init__.py`

`make_potion.py`

`potion.py`

tools

`__init__.py`

`ingredients.py`

`cooking.py`

# Advantage 1

—> know where to find items

e.g. wardrobe

- suit, shirts
- t-shirts
- socks, underwear

same concept applies to code

—> specific module names

# Advantage 2

- it makes all of your code **installable\***
- which makes all of your code **importable**

```
Terminal
> pip install brewing
>
> python
>>> import brewing
>>> brewing.brew_a_potion()
```

\* (need a few other changes we will go over)

# Advantage 2

- it makes all of your code **installable\***
- which makes all of your code **importable**

```
Terminal
> pip install brewing
>
> python
>>> import brewing
>>> brewing.brew_a_potion()
```

\* (need a few other changes we will go over)

?

Importing code from modules

# Importing modules

- you can always import code from other modules (.py files) in your ***current directory***
- Importing a module will execute all the code in the module (including print statements, unless you import specific objects)

# Importing modules

- you can always import code from other modules (.py files) in your ***current directory***
- Options for e.g. importing *eternal\_flame*

# Importing modules

- you can always import code from other modules (.py files) in your **current directory**
- Options for e.g. importing *eternal\_flame*

1. `import cooking`

2. `import cooking as cook`

3. `from cooking import eternal_flame`

4. `from cooking import *`

# Importing modules

- you can always import code from other modules (.py files) in your **current directory**
- Options for e.g. importing *eternal\_flame*

1. <code>import cooking</code>	+ <code>cooking.eternal_flame</code>
2. <code>import cooking as cook</code>	+ <code>cook.eternal_flame</code>
3. <code>from cooking import eternal_flame</code>	+ <code>eternal_flame</code>
4. <code>from cooking import *</code>	+ <code>eternal_flame</code>

# Importing modules

- you can always import code from other modules (.py files) in your **current directory**
- Options for e.g. importing *eternal\_flame*

1. <code>import cooking</code>	+ <code>cooking.eternal_flame</code> + <code>cooking.fire</code>
2. <code>import cooking as cook</code>	+ <code>cook.eternal_flame</code> + <code>cook.fire</code>
3. <code>from cooking import eternal_flame</code>	+ <code>eternal_flame</code> X <code>fire</code>
4. <code>from cooking import *</code>	+ <code>eternal_flame</code> + <code>fire</code>

# Importing modules

- you can always import code from other modules (.py files) in your **current directory**
- generally:

1. `import module-name` + `module-name.object`

2. `import module-name as abbr` + `abbr.object`

3. `from module-name import object` + `object`

4. ~~`from module-name import *`~~

# names & mains

any code running under `if __name__ == "__main__":`

- will be ignored when importing
- will be executed when the module is run as a script

```
if name == "__main__":  
    i_will_not_be_imported = True  
    print("Not printing when importing")  
    print("But printing when run as script")
```

# Importing a package

- you can always import a package that is located in the directory the script is located in
- Modules in the package are bound to the package name
- If the `__init__.py` file is empty

1. `import package` -
2. `import package.module` + `package.module.object`
3. `from package.module import object` + `object`
4. `from package.subpackage.module`  
`import object` + `object`

# Importing

- Follow the instructions in  
**Exercise Importing.md**

(There is no need to submit a pull request for this exercise)

?

**pip editable installation**

# Knowledge needed

- what happens when a package is installed?
- what does an editable pip installation do?
- what are the requirements for this?

# Available packages

- **core packages** e.g. time, math, os, ...  
(come with Python, no installation needed)
  - **installed packages** e.g. numpy, scipy, ...  
(packages are downloaded to a system location  
e.g. /Library/Frameworks/Python.framework/Versions/3.9/lib/python3.9/site-packages  
which is on the Pythonpath => Python can find it)
  - **current directory**
- All packages which fall under these categories can be imported

# Available packages

brewing  
package

- **core packages** e.g. time, math, os, ...  
(come with Python, no installation needed)
  - **installed packages** e.g. numpy, scipy, ...  
(packages are downloaded to a system location  
e.g. /Library/Frameworks/Python.framework/Versions/3.9/lib/python3.9/site-packages  
which is on the Pythonpath => Python can find it)
  - **current directory**
- All packages which fall under these categories can be imported

# Available packages

**brewing  
package**

- **core packages** e.g. time, math, os, ...  
(come with Python, no installation needed)
  - **installed packages** e.g. numpy, scipy, ...  
(packages are downloaded to a system location  
e.g. /Library/Frameworks/Python.framework/Versions/3.9/lib/python3.9/site-packages  
which is on the Pythonpath => Python can find it)
  - **current directory**
- All packages which fall under these categories can be imported

# Installing other packages

- Options to install a package using **pip**

**Option 1:** if package is included in PyPI

```
pip install numpy
```

**Option 2:** install from a VCS like git

```
pip install git+https://github.com/<user>/<package-name>.git
```

# Installing other packages

- You can install Python packages in your terminal using a package manager

## **pip**

standard package manager for  
Python

can install packages from PyPI  
(Python Package Index) or from VCS  
e.g. github

## **conda**

open source package manager/  
environment manager

can install packages which were  
reviewed by Anaconda

# Installing other packages

- You can install Python packages in your terminal using a package manager

## pip

standard package manager for Python

can install packages from PyPI (Python Package Index) or from VCS e.g. github

## conda

open source package manager/  
environment manager

can install packages which were reviewed by Anaconda

# Knowledge needed

- what happens when a package is installed?
- what does an editable pip installation do?
- what are the requirements for this?

# Knowledge needed

- what happens when a package is installed?
- what does an editable pip installation do?
- what are the requirements for this?

# Pip editable install

You can import the package you are currently working on as if it were a package you downloaded.

—> This lets you use your own code as any other package you installed

Advantages:

1. you can **import** the objects in the package **from any directory**  
(no longer bound to the directory which contains the package)
2. at the same time you can keep your project in your current directory
3. you use your code as someone else would use it, which forces you to write it in a more usable way

# Importing own project

- Options to install a package using **pip**

**Option 1:** if package is included in PyPI

```
pip install numpy
```

**Option 2:** install from a VCS like git

```
pip install git+https://github.com/<user>/<package-name>.git
```

**Option 3:** install your package with -e (--editable) option

```
pip install -e <path-to-package>
```

# Knowledge needed

# Requirements

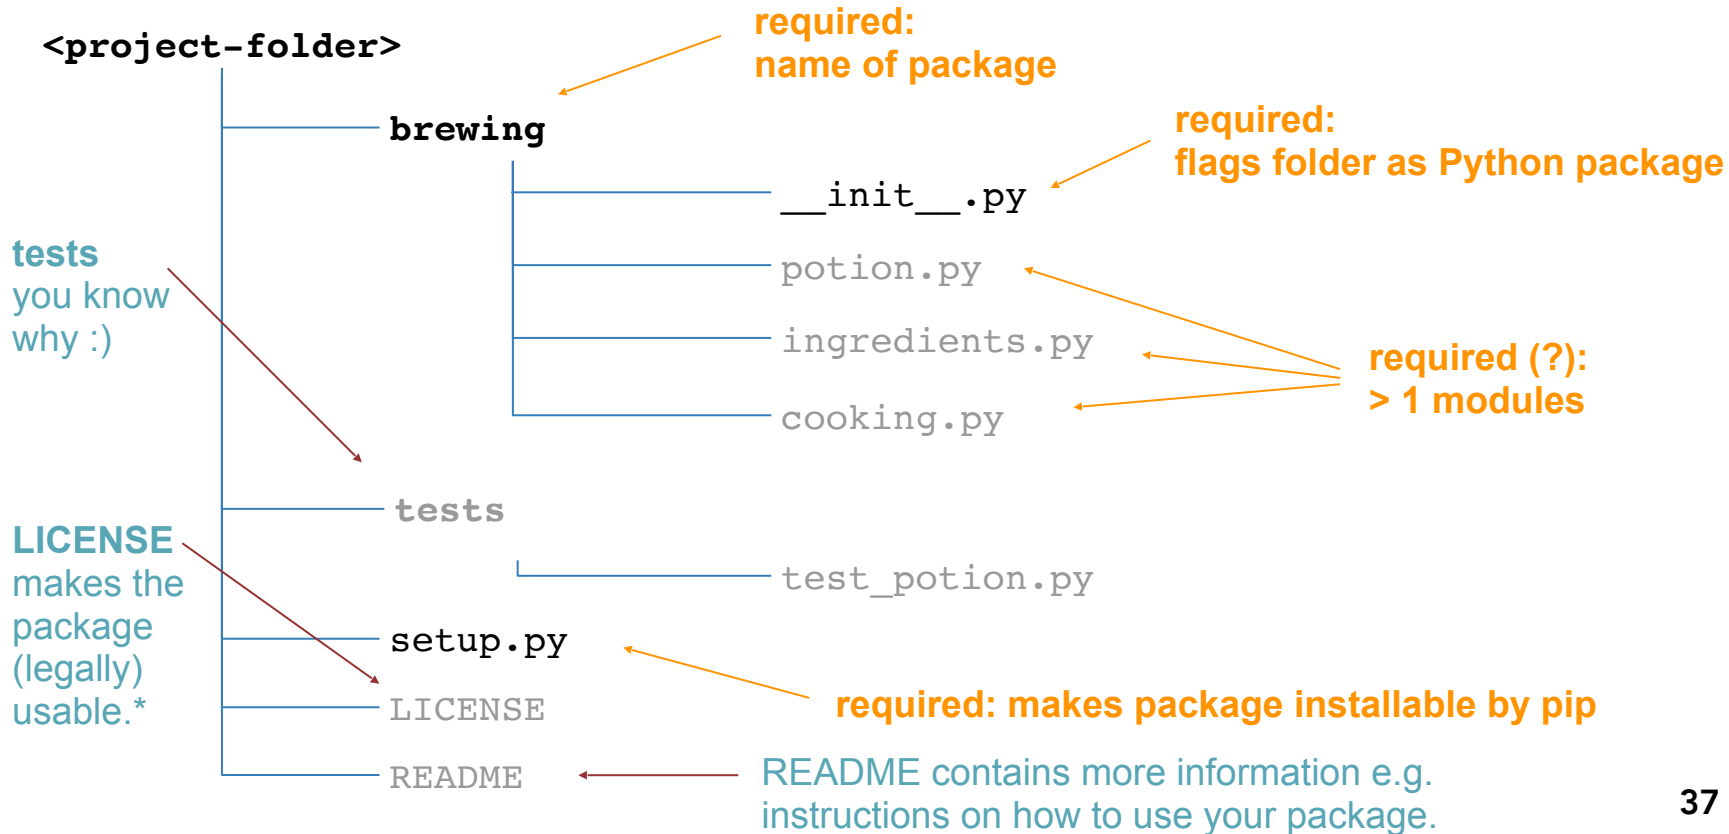

**<project-folder>**

# Requirements

# Requirements

\* pick one from [choosealicense.com](https://choosealicense.com)

# Setup.py

- The setup function receives package information and package meta data
- required entries: name, version, packages(/modules)
- **install\_requires** not optional if code relies on other packages to work (go through modules and update regularly, don't just copy '> pip freeze')  
-> can also go into separate requirements.txt file

```
from setuptools import setup, find_packages

with open('README.txt', 'r') as fh:
    long_description = fh.read()

setup(
    name = 'potions',
    version = '0.1.0',
    packages = find_packages(),
    author = 'ASPP 2021',
    author_email = 's.snape@hogwarts.ac.uk',
    description = 'an example python package',
    long_description = long_description,
    license = 'MIT',
    url = 'https://github.com/ASPP/2021-bordeaux-ODD.git',
    install_requires = ['numpy >= 1.13.0',
                        'matplotlib ~= 2.1.0'],
)
```

# Setup.py

                        'matplotlib ~= 2.1.0'],
)
```

# Pip editable installation

- `pip install -e <path-to-folder-above-brewing>`

or in the directory above `brewing`

`pip install -e .`

- Follow the instructions in  
**Exercise: Editable installation**

(There is no need to submit a pull request for this exercise)

?

how to develop code if it's in a package

# Workflow (realistic?)

## ① Create

Set up folder structure

Create files:  
`__init__.py`  
`setup.py`  
README  
LICENSE

Make installable  
at this point

## ② Build & Test

## ③ Publish

In `setup.py`  
update:  
version  
requirements

Update README

# Write your function

- Write the last remaining **potion making function** we need before sharing the package

Exercise:

- Create a branch with a unique name
- Follow the instructions in **Exercise Workflow** to write and test a function to make a “Python expert” potion
- Create a Pull Request

?

documentation

# Documentation

- Documenting your code provides a way of making your code **usable for future you and others**
  - **Comments** (#): describe what a line (or multiple lines of code do); notes to self
  - **Function/method docstring** ("""): purpose of function + params / return
  - **Module docstring** ("""): what's in this file

```
""" Module docstring """  
  
def add_points(house_points,  
               points=0):  
    """ Function docstring """  
    # comment  
    points += 1000  
    return house_points + points
```

# NumPy style

- triple double quotes below declaration
- The first line should be a short description
- If more explanation is required, that text should be separated from the first line by a blank line
- Specify Parameters and Returns as  
    name : type  
        description  
(put a line of --- below sections)
- Each line should begin with a capital letter and end with a full stop
- access docs:  
    pydoc3 <module>.<object>

```
""" This module demonstrates docstrings. """

def add_points(house, house_points, points=0):
    """ Adds up points for house cup.

    If the house is Gryffindor, Dumbledore adds
    1000 points no matter what.

    Parameters
    -----
    house_points : int
        Current house cup score.
    points : int, optional
        New points to be added/ subtracted.

    Returns
    -----
    int
    """
    if house == "Gryffindor":
        points += 1000
    return house_points + points
```

# Typing

- you can declare the type of the function argument
- the package *mypy* checks whether the types make sense
- Be aware that this might be a pain to maintain if you change your functions often and pass complicated objects...  
`tuple[int, dict[str, str]]`

```
""" This module demonstrates docstrings. """

def add_points(house: str,
               house_points: int,
               points: int = 0)
    -> int:
    """ Adds up points for house cup.

    If the house is Gryffindor, Dumbledore adds
    1000 points no matter what.

    Parameters
    -----
    house_points : Current house cup score.
    points : optional; New points to be added
    """

    if house == "Gryffindor":
        points += 1000
    return house_points + points
```

# Document your function

- Document the function you just wrote according to the instructions in **Exercise Documentation**.
- Use the same Pull Request

# Keeping track of your docstrings

- Most commonly used hosting websites: facilitate building, versioning, and hosting
  - [github.io](https://github.io)
  - [readthedocs.org](https://readthedocs.org)
- Automate documentation
  - [Sphinx](#): a package to collect docstrings and create a nicely formatted documentation website

# Virtual Environments

What is a virtual environment?

- A semi-isolated python environment -> you cannot access packages (libraries and their dependencies) installed in other environments.
- packages are installed inside a project-specific virtual environment folder (not added to general python path)
- If you break something, you can start over easily

# Virtual Environments

- Create and activate a virtual environment following the directions in **Exercise Virtual Environments.md**
- See what changed with regard to the Python interpreter and the installed packages

?

Summary

# Circle back

- **Organising** helps **you** and **future you** (and **other people**)

- following a **package folder structure** makes it easy to find objects
- creating a package will standardise the **import** statements
- doing an **editable install** will enable you to use it as you would do any package (e.g. from any directory) -> as another person would
- **documenting** your code will let anyone read your code more easily
- Using **virtual environments** will isolate your projects from each other and increase your chances of having your code work properly
